Linear dispersions in two-dimensional materials: a crystal with symmetry pbma1'as an example

Tuesday 30 August 2022 17:00 (15 minutes)

Symmetry determines forms of band structures in the vicinity of special points in the reciprocal space of one-, two- and three-dimensional materials. After short introduction to the complete classification of linear dispersions in 2D materials,[1] we will focus on a particular example. A tight binding model on a crystal with four sites per primitive cell that belongs to grey layer single group *pbma* (45.2.315 or *pbma*1' in the magnetic layer groups notation of Ref. [2]) is calculated. Fortune teller states are obtained in the Brillouin zone corners, as predicted[3,1] by group theory for non-magnetic materials with negligible spin-orbit coupling. We will discuss possible realizations of this model in realistic and hypothetical materials.
